## Introduction - About Bengaluru, India

- Bangalore, officially Bengaluru, the capital of the Indian state of Karnataka.
- With a population of over ten million, a megacity, the third-most populous city and fifth-most populous urban agglomeration in India.
- Widely regarded as the "Silicon Valley of India"
- One of the most productive metro area of India.
- Home to many educational and research institutions in India.
- Numerous state-owned aerospace and defence organisations are located in the city.
- Bangalore was the fastest-growing Indian metropolis after New Delhi between 1991 and 2001, with a growth rate of 38% during the decade.
- The Bruhat Bengaluru Mahanagara Palike (BBMP, Greater Bangalore Municipal Corporation) formed with 100 wards of the erstwhile Bangalore Mahanagara Palike currently has 198 wards.

## Introduction - About Bengaluru, India

- A demographically diverse city, Bangalore is the second fastest-growing major metropolis in India.
- With a population of 8,443,675 in the city and 10,456,000 in the urban agglomeration, up from 8.5 million at the 2011 census, Bangalore is a megacity, and the third-most-populous city in India and the 18th-most-populous city in the world.
- Bangalore's rapid growth has created several problems relating to traffic congestion and infrastructural obsolescence that the Bangalore Mahanagara Palike has found challenging to address.
- The unplanned nature of growth in the city resulted in massive traffic gridlocks that the municipality attempted to ease by constructing a flyover system and by imposing one-way traffic systems.
- Some of the flyovers and one-ways mitigated the traffic situation moderately but were unable to adequately address the disproportionate growth of city traffic.

#### Introduction - Problem Definition

#### Background

- To segregrate the neighborhoods in Bengaluru, India and to make use
  of this data to interpret the concentration of population.
- The distribution of population in neighborhoods has always been a topic of interest to various government/private agencies.
- This project aims to provide useful insights in to how the neighborhoods are segregrated so that the planning for the above cited activities can be done more effectively.
- As a representative entity, Bengaluru, India is chosen as the target location.

#### Business Problem

To segregrate neighborhoods based on location data and along with geospatial and population statistics, arrive at useful insights that can aid different agencices to implement their schemes more effectively.

#### Introduction - Problem Definition

#### Description of the problem

The problem consists of following subproblems:

- Get Data Source for Population/Equivalent for all neighborhoods in Bengaluru, India
- @ Get GeoJSON corresponding to neighborhoods in Bengaluru, India
- Get lattitude, longitude information for all neighborhoods using geocoder
- Get location data corresponding to all neighborhoods using Foursquare API
- Olean all data, explore them, extract features
- Arrive at appropriate methodologies to segregate neighborhoods
- Segregate neighborhoods using location data
- Analyse segregated neighborhoods data in conjuction with population data and interpret the results

#### **Data Sources**

#### 1. Demographic data of neighborhoods in Bengaluru, India

- PDF file obtained from website of Karnataka State Election Commission, Ward Wise Voters Data
- This data in tabular format is available as a pdf file and contains the total number of voters in each neighborhood and is representative of the population.

## 2. GeoJSON corresponding to neighborhoods in Bengaluru, India

- BBMP.GeoJSON
- This dataset is shared under Creative Commons Attribution-ShareAlike 2.5 India license

#### **Data Sources**

#### 3. Lattitude, Longitude information for all neighborhoods

- Geocoder was initially used to get this information.
- Given that this package can be very unreliable, in this case it was not possible to get the geographical coordinates of the neighborhoods accurately using the Geocoder package, hence it was tweaked from GeoJSON file.

#### 4. Location data corresponding to all neighborhoods

- Foursquare API is used to get venues and categories for each neighborhood.
- With neighborhood names and latitude-longitude information, Foursquare API is used to get location data consisting of upto 50 venues within a 2km radius from given geospatial coordinates corresponding to each neighborhood.

## Data Description & Data Cleaning-1

#### 1. Demographic data of neighborhoods in Bengaluru, India

- The voters list summary as of 2010 downloaded from Karnataka Election Commission Website as pdf file.
- This PDF file consisting of 6 pages was converted to csv file offline and this CSV file was used for the project.
- Table has 14 columns including ward no, ward name, male, female and total voters count for selection, addition, deletion and net total.
- All columns other than ward name and net total are dropped.
- The table consists of 198 rows each corresponding to one ward.
- The ward name has leading ward no information which is stripped.
- The final dataframe consists of ward name and total voters information.

#### Data Description-1

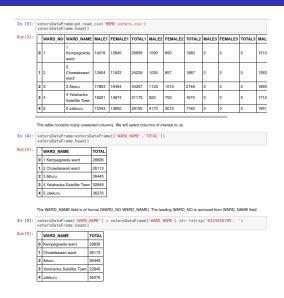

Figure: BBMP.csv after Data Cleaning

## Data Description-2

## 2. GeoJSON corresponding to neighborhoods in Bengaluru, India

- This dataset is shared under Creative Commons Attribution-ShareAlike 2.5 India license
- This dataset is used to generate chloropleth map of Bengaluru with ward boundaries and total voters from data frame of data source 1.

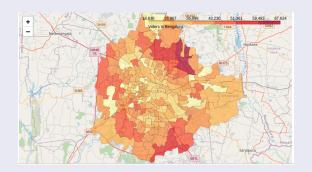

Figure: Chloropleth of Bengaluru

## Data Description - 3

- Geocoder was initially used to get this information.
- The latitude, longitude information was obtained for 186 out of 198 wards. Suitable steps needs to be taken at later stage to address these 12 missing data points.

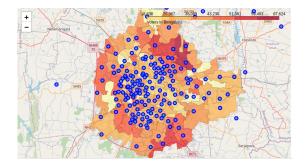

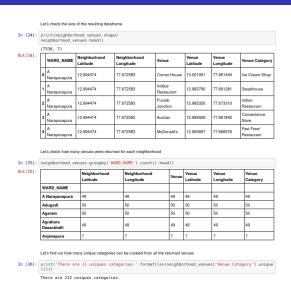

Figure: Geocoder outputs plotted over Chloropleth

## Data Description - 4

#### 4. Location data corresponding to all neighborhoods

- Foursquare API is used to get venues and categories for each neighborhood.
- With neighborhood names and latitude-longitude information, Foursquare API is used to get location data consisting of upto 50 venues within a 2km radius from given geospatial coordinates corresponding to each neighborhood.
- A total of 7536 venues were returned with the given search criteria.
- Venues were returned for all 198 wards.
- A total of 212 unique categories of venues were identified which will form our feature set.

  - Future Directions

## Data Analysis - Data Source 3

- Geocoder provided latitude, longitude information 186 of 198 wards.
- Chloropleth plotted with the available data points
- The coordinates were not accurate with few being even outside the chloropleth.

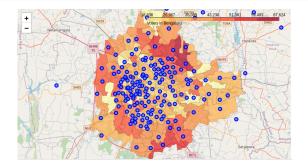

Figure: Geocoder outputs plotted over Chloropleth

## Data Analysis -Data Source 3

- From box plots it is evident that data is having many outliers.
- Missing data, and inaccurate results makes this data source unreliable.
- The geographical coordinates of the neighborhoods were therefore tweaked from GeoJSON file.

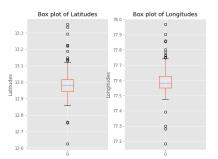

Figure: Box plot for Geocoder outputs - many outliers far away from quartiles

- GeoJSON file (Data Source 2) file consists of feature properties which includes ward name, latitude, longitude which can serve our purpose given the fact that geocoder data pproved to be unusable.
- The GeoJSON file was parsed to obtain the required information.
- The latitude, longitude information was obtained for all 198 wards.
- However on merging by ward names, it was observed that only 181 wards are getting parsed correctly.
- Using outer join, the remaining ward names were seen and it was noticed that there are slight mismatches in names between the data sets for 17 wards.
- A dictionary was prepared mapping these 17 ward names between two data sets and the data was updated and merged successfully.

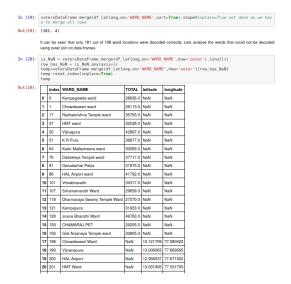

Figure: Data Parsing Error in Ward\_Names

23 / 42

```
In [211: templ=sorted(temp[['WARD NAME']][0:17].values.tolist())
          temp2=sorted(temp[['WARD_NAME']][17:34].values.tolist())
          dictionary =dict()
          for i in range (0,len(temp1)):
             dictionary[str(temp2[i][0])]=str(temp1[i][0])
          dictionary
Out[21]: {'Chamraiapet': 'CHAMARAJ PET'.
           'Chowdeswari Ward': 'Chowdeswari ward'.
           'Dattatreya Temple': 'Dattatreya Temple ward',
           'Dharmaraya Swamy Temple': 'Dharmaraya Swamy Temple Ward'.
           'Gali Anjenava Temple ward': 'Gali Anjaneva Temple ward'.
           'Garudachar Playa': 'Garudachar Palya',
           'HAL Airport': 'HAL Airport ward',
           'HMT Ward': 'HMT ward',
           'Jnana Bharathi ward': 'Jnana Bharathi Ward',
           'K R Puram': 'K R Pura'.
           'Kadu Malleshwar Ward': 'Kadu Malleshwara ward'.
           'Kempapura Agrahara': 'Kempapura',
           'Kempegowda Ward': 'Kempegowda ward',
           'Radhakrishna Temple Ward': 'Radhakrishna Temple ward',
           'Sriramamandir': 'Sriramamandir Ward'.
           'Viinanapura': 'Viiinapura'.
           'Vrisabhayathi Nagar': 'Vrisabhayathi'}
          Now replace these WARD NAMES in lattong with corresponding names in voters
In [22]: for i in dictionary:
             df latlong[['WARD NAME']]=df latlong['WARD NAME'].str.replace("{}".format(i).dictionary[i])
         Now check if all ward names are decoded correctly

#### Feature Extraction & Normalization

### Onehot Encoding and Normalization

- The 212 features were encoded by 7536 venues using onehot encoding.
- The venues were grouped by ward names, normalizing the values in the go, leaving us with 198 rows with 212 features each.
- The data frame with top ten venues per ward was formed for later analysis

#### Feature Extraction & Normalization

```
In [431: num top venues = 10
          indicators = ['st', 'nd', 'rd']
          # create columns according to number of top venues
          columns = ['WARD NAME']
          for ind in np.arange(num top venues):
              trv:
                   columns.append('{}{} Most Common Venue'.format(ind+1, indicators[ind]))
              except:
                   columns.append('{}th Most Common Venue'.format(ind+1))
          # create a new dataframeStatistics
          neighborhoods venues sorted = pd.DataFrame(columns=columns)
          neighborhoods venues sorted['WARD NAME'] = neighborhood grouped['WARD NAME']
          for ind in np.arange(neighborhood grouped.shape[θ]):
               neighborhoods venues sorted.iloc[ind, 1:] = return most common venues(neighborhood grouped.i
          loc[ind, :], num top venues)
          neighborhoods venues sorted.head()
Out[43]:
                          1st Most
                                    2nd Most

## K-Means Clustering

#### Finding optimum k

- Elbow method was used to arrive at an optimum value of k for k-means clustering.
- Based on elbow method a cluster size of 3(based on inertia) or 4(based on distortion) can be chosen. k=4 is chosen.

## **Examining Results**

- Clusters 1 and 2 are concentrated towards the city, whereas clusters 3 and 4 are formed by wards to the exterior of the city.
- Clusters 1 and 2 include different wards covering different voter counts whereas clusters 3 and 4 mostly include wards where the no of voters is less.

#### Conclusion

- Inner wards with more population are clustered together based on the feature set which includes venue categories. This is intuitive since more locations/venues will be available towards the centre of city as well as places where population is more.
- Outer wards with lesser population are clustered together based on the feature set which includes venue categories. This is intuitive since lesser locations/venues only will be available towards the outskirts of city as well as places where population is less.
- Thus the results validate our initial premise that the population data in conjuction with location data will give us insights in to how clusters are formed around cities.

#### **Future Directions**

- The study was based on Bengaluru, India taken as a representative entity. The study can be extended to more cities.
- More variables can be brought in to the feature set to get more insights in to the data.
- Location data can be made more specific to search for business avenues in different clusters.
- ...And keep imagining, even the sky is not the limit.
